ATTENTION

This is a USER program. Other than requiring that it conform to submittal and review standards, no quality control has been imposed upon this program by DECUS.

The DECUS Program Library is a clearing house only; it does not generate or test programs. No warranty, express or implied, is made by the contributor, Digital Equipment Computer Users Society or Digital Equipment Corporation as to the accuracy or functioning of the program or related material, and no responsibility is assumed by these parties in connection therewith.

FORTRAN-D 4K OVERLAYINGS TO CHAIN PROGRAMS

ABSTRACT

The overlayings add five new statements to Fortran-D 4K supplied by Digital Equipment Corporation.

This new version of Fortran is designed to segment large programs and/or to use a large amount of data.

EXPLANATION OF NEW STATEMENTS AND THEIR USE

The first two statements "CALL N" and "RETURN" consent the use of subroutines (see DECUSCOPE, Vol. 9, No. 3, page 6, by Willen L.).

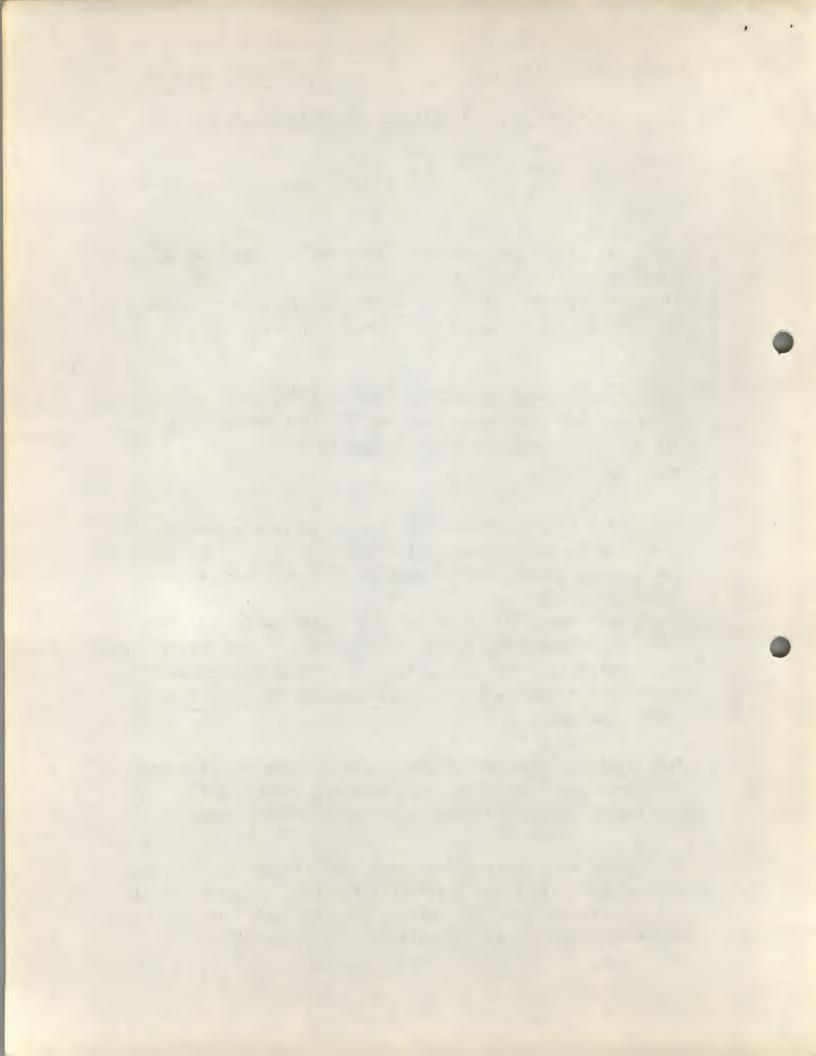

The "CHAIN NAME" statement is used to chain the current segment with the segment called "NAME".

The filname "NAME" has the same restrictions imposed by DECtape Monitor System.

These overlayings allow to use the whole DECtape No. 7 to store a large amount of data. The DECtape is not used in the usual file oriented way for I/O of data and the same location (of DECtape) may be used whether by "WRITE" or by "READ" statements.

The "REWIND" statement is used to read again the data beginning from the first block. The data are stored in the DECtape in sequential way (not directly addressable).

The "BLOCK OUT" statement is used whenever we wish to read data immediately after their writing; this statement is necessary because the I/O routines transfer only full blocks of data, from tape to I/O buffers (and vice versa).

To write and use chaining programs, for every segment, proceed in this way:

1) Use Edit to create the source segment.

Remember that:

- a) the first instruction of every segment must be "DEFINE DECTAPE";
- b) the "DIMENSION" statement allows to create a COMMON area between the chaining segments. This statement must precede the first executable instruction in every segment and the common variable (integer, floating or subscritted) must be written on the same sequence;
- c) the "STOP" statement must be used only on the last segment; or if an error condition occurs;
- d) the "REDWIN" statement "READ 3, f, list" must precede the first instruction of the program if we wish to read data written by the program.
- 2) Use FORTRAN-D Compiler to convert the source into object segment. The filname must be the same employed on "CHAIN" statement of calling segment.
- 3) To execute Fortran program, call FOSL as usual; reply to its requests of input with the name of the first segment of the program, and then to the option request with "S".

EXAMPLE:

- . FOSL
- * IN-S: (filname of the first segment)
- *
- * OP-S
- ↑ (↑P Typed here)

The FOSL loads the first segment and executes it.

The next segment, if there is one, is loaded and started

automatically when the "CHAIN" statement is met.

If the segment is not in the system, FOSL andwers with the unfound name followed by a question mark.

EXAMPLE OF USE

If a program is divided in two segments called "PRW1" and "PRW2" in the following form:

Segment PRW1

DEFINE DECTAPE
DIMENSION A(3) , FXQ(15) , BP(27)

CHAIN PRW2

Segment PRW2

DEFINE DECTAPE
DIMENSION B(3), AQZ(15), PR(27)

STOP END

to execute all the Fortran program it is necessary to load the first segment (PRWI) with the FOSL. Infact, during the execution of PRWI when the "CHAIN PRW2" statement is met, the segment PRW2 is loaded and then executed.

The "DIMENSION" statement creates a common area for the variable (A and B; FXQ; BP and PR).

The use of the overlayings and of the new statements is demonstrated by the program which fits a Gaussian to set of experimental data, put as example.
